(54) Title: AUTO REALIGNMENT OF MULTIPLE SERIAL BYTE-LANES

(57) Abstract: Described is a data communication arrangement (100) with a transmit module adapted to convert parallel data words (102) into a plurality of serial data streams (122, 124, 126, 128), the transmit module arranged in a plurality of groups, with each group including a data-carrying line (122, 124, 126, 128). A receive module (200) is adapted to collect the digital data carried from the transmit module (100) over the plurality of data-carrying lines (122, 124, 126, 128). The receive module (200) detects a frequency compensation code, and in response provides a code-detected signal used for aligning the data back into parallel words and mitigating skew-caused re-training and configuration sequences. The receive module (200) may continuously check alignment between the groups and autonomously correct alignment of the plurality of data groups.
